ABSTRACT. *Eleocharis laeviglumis* is a new species from the Brazilian flora. This species belongs to *Eleocharis* subg. *Limnochloa* (P. Beauvois ex T. Lestiboudois) Torrey and is very similar to *Eleocharis elongata* Chapman. The new species differs from all species of *Eleocharis* R. Brown by culms terete, not septate; lower scale fertile; upper scales cartilaginous, smooth, without prominent veins, with submarginal band vinaceous to brown, hyaline margin conspicuous and abruptly differentiated from the rest of scale; slender bristles; achenes trigonous, reticulate, and without a short neck on the apex. Morphological description, illustration, data on habitat, and comparison with the similar species are presented.

RESUMO. *Eleocharis laeviglumis* é uma nova espécie descrita para a flora brasileira. Esta espécie pertence a *Eleocharis* subg. *Limnochloa* (P. Beauvois ex T. Lestiboudois) Torrey e é muito semelhante a *Eleocharis elongata* Chapman. A nova espécie diferencia-se das outras espécies do gênero *Eleocharis* pelos colmos cilíndricos, não septados; gluma inferior fértil; glumas superiores cartilaginosas, lisas, de nervuras inconspícuas, com uma faixa submarginal vinácea a castanha, margem hialina desenvolvida e nitidamente delimitada do restante da gluma; cerdas hipóginas tenues; aquênios trigonos, reticulados, e sem colo no ápice. Apresenta-se a descrição morfológica, ilustração, dados sobre o habitat, e uma comparação com a espécie similar.

Key words: Brazil, Cyperaceae, *Eleocharis*, *Limnochloa*.

Eleocharis is a worldwide genus that includes ca. 200 species (González-Elizondo & Tena-Flores, 2000) with a remarkable richness in tropical and subtropical America (Goetghebeur, 1998). Distinctive features,

such as unbranched aerial culms, leaves reduced to tubular sheaths, inflorescence constituted of one spikelet on the apex of culms without involucral bracts, and style-base enlarged and persistent on the achene, are uniformly found in this genus.

Almost all species of *Eleocharis* are restricted to wetlands, often in muddy soils that are temporarily wet or inundated.

There are some taxonomic treatments of *Eleocharis*, such as Svenson (1929, 1932, 1934, 1937, 1939), Barros (1947, 1960), González-Elizondo (1994), González-Elizondo and Reznicek (1998), and Smith et al. (2005), based on a regional or a worldwide review of the species.

The supraspecific classifications of *Eleocharis* (Svenson, 1939; Kukkonen, 1990; González-Elizondo & Peterson, 1997) are based on morphological data. A study using DNA sequences (Roalson & Friar, 2000) verified that some groups proposed in recent classifications are probably monophyletic.

***Eleocharis laeviglumis* Trevisan & Boldrini, sp. nov.** TYPE: Brazil. Rio Grande do Sul: mun. Santa Vitória do Palmar, BR 471, 32°45'00.1"S, 52°38'51.4"W, 26 Nov. 2004, I. Boldrini, E. N. Garcia & R. Trevisan 1311 (holotype, ICN; isotype, K, MO). Figure 1.

Eleocharis laeviglumis Trevisan & Boldrini ab omnibus speciebus generis culmis teretibus, non septatis, squama inferna fertili, squamis superis cartilagineis, laevis, nervis inconspicuis, fasciis submarginalibus vinaceis vel brunneis, marginibus hialinis conspicuis distinete a parte inferna squamis, setis hypogynis tenuibus, acheniis trigonis, reticulatis sin collis in apicibus differt.

Perennial, erect from creeping and ligneous rootstock, often with elongate rhizomes 1.5–2.5 mm wide, with internodes 1.2–2.2(–3) cm long, scales 5–

Figure 1. *Eleocharis laeviglumis* Trevisan & Boldrini. —A. Habit. —B. Spikelet. —C. Upper scale, dorsal view. —D. Achene. —E. Achene, cross section. —F. Culm, cross section. —G. Sheath, dorsal view of the apex. B, C, and F drawn from R. Trevisan & I. Boldrini 32 (ICN); D and E from R. Trevisan et al. 324 (ICN); and A and G from R. Trevisan et al. 329 (ICN).

6 mm long; culms 30–65 × 0.1–0.3 cm, terete, non-septate, generally nodulate, internally spongy; sheaths 7–15 cm long, apex oblique acuminate. Spikelets 10–23 × 2.2–3.5 mm, lanceoloid to cylindric, as wide as

their culms, 20- to 50-flowered, not proliferous, stramineous to yellowish brown; lower scale fertile, coriaceous, ovate, apex obtuse, green, with conspicuous hyaline margin; upper scales 3.5–4(–5) × 2–

2.3 mm, cartilaginous, strongly imbricate, elliptic to obovate, apex obtuse, spiralate, appressed, not keeled, stramineous to yellowish brown, inconspicuous nerved, smooth, with submarginal band vinaceous to brown, hyaline margin conspicuous and abruptly differentiated from the rest of scale; *bristles* 6 or 7, white to yellowish white, slender, somewhat denticulate, equaling or exceeding the achene including the style-base; *stamens* 3, anthers 1.3–1.5 mm long; *style* trifid. *Achenes* 1.2–1.5 × 0.8–1 mm, trigonous, obovoid to obpyriform, reticulate with 8 to 10 rows of coarse transversely linear cells on the adaxial face, light green to stramineous; *style-base* 0.6–0.8 mm long, not confluent but separated from the achene by a small constriction, pyramidal elongate, usually curvate, green to brownish green.

Etymology. The epithet refers to the smooth scales. This character is not common in *Eleocharis* subg. *Limnochloa*.

Habitat and distribution. The species is very common in permanently flooded environments in coastland regions in Rio Grande do Sul and Santa Catarina, Brazil. The plants generally have culms partially submerged, forming clonal masses. Developed rootstocks are not present in young individuals. This structure was observed only in old plants.

According to the supraspecific classification proposed by González-Elizondo and Peterson (1997), *Eleocharis laeviglumis* belongs to *Eleocharis* subg. *Limnochloa* (P. Beauvois ex T. Lestiboudois) Torrey sect. *Limnochloa* (P. Beauvois ex T. Lestiboudois) Bentham & Hooker f. The new species is included in this subgenus on the basis of the following features: lower scale is fertile and appears to be a continuation of the fertile culm; upper spikelet scales are indurate, are not keeled, and have a distinct hyaline margin; ornamentation on the achenes appears as polygonal cells.

Eleocharis elongata Chapman is very similar to the new species, but differs by slender (0.4–1.5 mm) and flaccid culms, striate and loosely imbricate upper scales, achene apex constricted to short neck, and style-base 0.2–0.5 mm long.
